

Case Study Report: Banking Transaction Processing Using Merge Sort

Title :

Banking Transaction Processing Using Merge Sort

Description of the Real-World Problem

Modern banking systems process millions of financial transactions every day through ATMs, online banking, mobile banking, UPI payments, credit/debit cards, and fund transfers. Each transaction is recorded with a timestamp and must be organized in chronological order for auditing, account reconciliation, fraud detection, and report generation. As the volume of transactions continues to grow, manually sorting this data becomes impossible, making efficient sorting techniques essential. One of the major challenges is handling a large number of transactions while maintaining accuracy and speed. In many cases, multiple transactions may have the same timestamp, so the sorting algorithm must preserve their original order. This property, known as stability, is important because it ensures that transaction records remain consistent and reliable for financial auditing and customer account verification.

Merge Sort is an ideal solution for this problem because it uses the divide-and-conquer approach to split large datasets into smaller parts, sort them efficiently, and merge them back into a correctly ordered list. It guarantees $O(n \log n)$ time complexity in all cases and provides stable sorting, making it highly suitable for banking systems that require fast, accurate, and reliable transaction processing.

Problem Statement :

Modern banking systems generate millions of transactions every day, making it difficult to sort and manage transaction records efficiently. The system must organize these transactions based on their timestamps to support auditing, fraud detection, account reconciliation, and report generation. As the volume of data increases, traditional sorting methods become inefficient and time-consuming. The objective is to design an efficient solution using Merge Sort to sort large volumes of banking transactions. The solution should provide stable sorting, guarantee $O(n \log n)$ time complexity, and ensure reliable performance for large-scale banking applications.

Algorithm Used :

The algorithm used in this case study is Merge Sort, a Divide and Conquer sorting algorithm. Merge Sort works by repeatedly dividing the list of banking transactions into smaller sublists until each sublist contains only one transaction. These smaller sublists are then merged in a sorted manner based on their timestamps to produce the final sorted list. The algorithm follows three main steps: Divide, Conquer, and Merge. First, the transaction list is divided into two equal halves. Next, each half is recursively sorted until individual elements remain. Finally, the sorted sublists are merged while maintaining the correct order of transactions, ensuring that transactions with the same timestamp remain in their original sequence.

Merge Sort is highly suitable for banking transaction processing because it guarantees $O(n \log n)$ time complexity in the best, average, and worst cases. It is also a stable sorting algorithm, making it ideal for applications where maintaining the original order of equal transactions is essential for accurate auditing and financial reporting.

Steps:

1. Divide the transaction list into two equal halves.
2. Recursively divide each half until only one element remains.
3. Merge the divided lists while arranging transactions in ascending timestamp order.
4. Continue merging until the complete sorted list is obtained.

Justification for Choosing the Algorithm (Why This Algorithm?) :

Merge Sort is chosen for banking transaction processing because it provides stable and efficient sorting, which is essential for handling financial records. In banking systems, multiple transactions may have the same timestamp, and Merge Sort preserves their original order, ensuring data consistency and accurate auditing. This stability makes it more reliable than many other sorting algorithms. Another reason for choosing Merge Sort is its guaranteed $O(n \log n)$ time complexity in the best, average, and worst cases.

Additionally, Merge Sort follows the divide-and-conquer strategy, which efficiently breaks large datasets into smaller parts, sorts them independently, and merges them into a final sorted list. Its predictable performance, scalability, and stability make it an ideal choice for banking systems used in auditing, fraud detection, report generation, and transaction management.

Complexity Analysis :

Case	Time Complexity
Best Case	$O(n \log n)$
Average Case	$O(n \log n)$
Worst Case	$O(n \log n)$

Space Complexity: $O(n)$

Explanation

- The list is repeatedly divided into halves ($\log n$ levels).
- At each level, merging takes $O(n)$ time.
- Therefore, the total time complexity becomes $O(n \log n)$.

Manual Execution (Step-by-Step Process) :

Input Transactions (Timestamps)

105, 101, 110, 102, 108, 101

Step 1: Divide

[105,101,110] [102,108,101]

Step 2: Divide Again

[105] [101,110] [102] [108,101]

Step 3: Divide Until Single Elements

[105] [101] [110] [102] [108] [101]

Step 4: Merge Sorted Lists

[101,105,110]

[101,102,108]

Final Merge

[101,101,102,105,108,110]

Observation :

The execution of Merge Sort shows that banking transactions are sorted accurately in ascending order of their timestamps while preserving the original order of transactions with identical timestamps. This confirms that Merge Sort is a stable sorting algorithm, which is essential for maintaining the integrity of financial records.

The divide-and-conquer approach enables the algorithm to efficiently process large volumes of transaction data by dividing the dataset into smaller parts and merging them in sorted order. This results in consistent $O(n \log n)$ performance, making Merge Sort highly effective for banking systems that require fast, reliable, and accurate transaction processing.

Applications :

- Banking transaction processing
- Financial auditing systems
- Payroll management
- Database record sorting
- E-commerce transaction processing
- Large-scale log analysis
- Data warehousing

Advantages :

- **Stable Sorting:** Maintains the original order of transactions with the same timestamp, ensuring accurate financial records.
- **Efficient Performance:** Guarantees $O(n \log n)$ time complexity in the best, average, and worst cases, making it suitable for large datasets.

- **Reliable for Large Data:** Efficiently handles millions of banking transactions without significant performance degradation.
- **Predictable Execution:** Provides consistent performance regardless of the input data, unlike some other sorting algorithms.
- **Suitable for External Sorting:** Works well when data is stored on external storage devices, making it ideal for large-scale banking and database applications.
- **Divide and Conquer Approach:** Breaks the problem into smaller subproblems, simplifying the sorting process and improving efficiency.

Limitations :

- Requires additional memory ($O(n)$).
- Slower than Quick Sort in some in-memory applications.
- Extra merging operations increase memory usage.
- Not suitable when memory availability is limited.

Comparison with Other Algorithms

Algorithm	Stable	Best Case	Average Case	Worst Case	Space Complexity
Merge Sort	Yes	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(n)$
Quick Sort	No	$O(n \log n)$	$O(n \log n)$	$O(n^2)$	$O(\log n)$
Heap Sort	No	$O(n \log n)$	$O(n \log n)$	$O(n \log n)$	$O(1)$
Bubble Sort	Yes	$O(n)$	$O(n^2)$	$O(n^2)$	$O(1)$
Insertion Sort	Yes	$O(n)$	$O(n^2)$	$O(n^2)$	$O(1)$

Screenshot of the Program :

The screenshot shows a web-based IDE with a file named 'main.c'. The code implements a merge sort algorithm. It includes `<stdio.h>` and defines a `merge` function that takes an array and indices for left, mid, and right. The main function calls `merge` with the array `arr` and indices `0`, `6`, and `6`. The output panel on the right shows the original transactions as '105 101 110 102 108 101' and the sorted transactions as '101 101 102 105 108 110'. A green message '=== Code Execution Successful ===' is displayed at the bottom of the output panel.

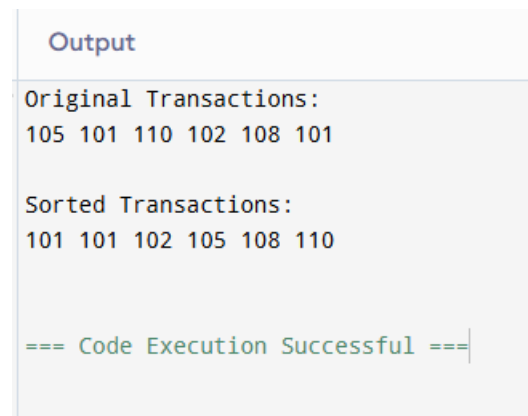

```
1 #include <stdio.h>
2
3 void merge(int arr[], int left, int mid, int right)
4 {
5     int i, j, k;
6     int n1 = mid - left + 1;
7     int n2 = right - mid;
8     int L[n1], R[n2];
9     for(i = 0; i < n1; i++)
10         L[i] = arr[left + i];
11     for(j = 0; j < n2; j++)
12         R[j] = arr[mid + 1 + j];
13     i = 0;
14     j = 0;
15     k = left;
16     while(i < n1 && j < n2)
17     {
18         if(L[i] <= R[j])
19         {
20             arr[k] = L[i];
21             i++;
22         }
23         else
24         {
25             arr[k] = R[j];
26             j++;
27         }
28         k++;
29     }
30     while(i < n1)
31     {
32         arr[k] = L[i];
33         i++;
34         k++;
35     }
36     while(j < n2)
37     {
38         arr[k] = R[j];
39         j++;
40         k++;
41     }
42 }
```

Original Transactions:
105 101 110 102 108 101

Sorted Transactions:
101 101 102 105 108 110

=== Code Execution Successful ===

Output Screenshot :

The screenshot shows the output of the program. It displays the original transactions as '105 101 110 102 108 101' and the sorted transactions as '101 101 102 105 108 110'. A green message '=== Code Execution Successful ===' is displayed at the bottom.

Original Transactions:
105 101 110 102 108 101

Sorted Transactions:
101 101 102 105 108 110

=== Code Execution Successful ===

Conclusion :

Merge Sort is an ideal algorithm for banking transaction processing because it provides stable sorting, consistent $O(n \log n)$ performance, and efficiently handles millions of transactions. Its divide-and-conquer approach ensures reliable sorting for auditing, reporting, and financial record management, making it one of the most suitable algorithms for large-scale banking systems.
